WARNING: If the information in these instructions is not followed exactly, a fire or explosion may result, causing property damage, personal injury or death.

- Do not store or use gasoline or other flammable vapors and liquids in the vicinity of this or any other appliance.
- WHAT TO DO IF YOU SMELL GAS:
  - Do not try to light any appliance.
  - Do not touch any electrical switch; do not use any phone in the building.
  - Immediately phone your gas supplier from another building. Follow the gas supplier’s instructions.
  - If you cannot reach your gas supplier call the fire department.

Installation and service must be performed by a qualified installer, service agency or the gas supplier.

INSTALLER: Inform and demonstrate to the user the correct operation and maintenance of the gas utilization equipment. Inform the user of the hazards of storing flammable liquids and vapors in the vicinity of this gas utilization equipment and remove such hazards. Affix this manual and associated literature adjacent to the conversion burner.

CODE COMPLIANCE IS THE SOLE RESPONSIBILITY OF THE INSTALLER.

USER: Retain this manual for future reference. If other than routine service or maintenance as described in this manual and associated literature is required, contact a qualified service agency. DO NOT ATTEMPT REPAIRS. An inadvertent service error could result in a dangerous condition.

SAFETY INFORMATION TERMS: The following terms are used to identify hazards, safety precautions or special notations and have standard meanings throughout this manual. They are printed in all capital letters using a bold typeface as shown below, and preceded by the exclamation mark symbol:

DANGER: Identifies the most serious hazards which will result in severe personal injury or death.

WARNING: Signifies hazards that could result in personal injury or death.

CAUTION: Identifies unsafe practices which would result in minor personal injury or product and property damage.
SPECIAL SPECIFICATIONS

The ECONOMITE Models 400-33 and F400-33 conversion burners with intermittent spark ignited pilot are adaptable to most gas utilization equipment, including gravity and forced circulation furnaces and boilers. They are particularly recommended for firing horizontal or down-draft equipment since they need no draft to maintain a pilot. Power burner design makes them perfectly suited for oil burner replacement, including rooftop and industrial applications.

II PREPARATION OF THE GAS UTILIZATION EQUIPMENT

Clean the gas utilization equipment combustion chamber, heat exchanger interior, and flue connections. Remove all adhering tars, scale, dirt and soot. Inspect for actual or potential leaks.

Cement all joints, including those in the heating appliance base and around the door frames, to prevent leakage into, or out of the combustion chamber.

The access or firing door should open easily to relieve pressure. If positive latches exist, they should be modified to permit easy opening; a spring loaded door holder is recommended.

On all boilers, make certain the pressure relief safety valve is in good operating condition.

III COMBUSTION CHAMBER

A combustion chamber liner is normally required to protect non-heat transfer surfaces and to provide a radiant bed for rapid heat transfer to the primary surfaces of the heat exchanger. In most cases the existing chamber liner can be used, if in good condition.

In the case of wet base boilers, where the entire firing chamber is comprised of heat exchange surfaces and no chamber liner was provided for oil firing, a liner is usually not required for the ECONOMITE. However, a liner or target wall may be necessary if the firing chamber is unusually short, in order to avoid excess flame contact on the heat exchanger walls or flueways.

If a built up chamber liner is required, use 2,300°F minimum insulating material.

The burner tube, or the stainless steel sleeve that is included with the burner, must be sealed air tight into the combustion chamber opening with refractory material as shown by Figures 1 and 2. The sleeve is preferred as it is designed to properly locate the end of the tube relative to the inside wall of the combustion chamber, and to permit burner removal without breaking the seal.

CAUTION: In no case should the burner tube be allowed to extend into the chamber proper; it must be set at least 1" short of the inside surface.

Special heat resistant alloy extension tubes and instructions are available for those applications where the burner tube is too short to reach the combustion chamber (such as old-fashioned gravity warm air furnace installations).

WARNING: BURNER CABINET MUST BE MOUNTED IN ORIENTATION SHOWN IN FIGURES 1 AND 2. ANY OTHER MOUNTINGS MAY CAUSE A DANGEROUS CONDITION, AND WILL VOID BURNER WARRANTY AND AGENCY APPROVALS. NON-STANDARD ARRANGEMENTS MAY BE AVAILABLE FOR SOME MODELS-CONSULT FACTORY FOR DETAILS IF REQUIRED.
IV  CHIMNEY, VENT CONNECTOR AND DRAFT CONTROL

⚠️ WARNING: The chimney shall be inspected for unsafe conditions such as deteriorated masonry and excessive soot or other blockage or potential blockage. Installation must conform with local codes or in the absence of local codes with NFPA , ANSI Z223.1 latest edition.

⚠️ WARNING: The vent connector shall not be connected to a chimney already venting solid fuel burning equipment, an incinerator or an open fireplace.

The Vent Connector shall be made of non-combustible, corrosion resistant material capable of withstanding the vent gas temperature produced by the gas utilization equipment and of sufficient thickness to withstand physical damage.

The Vent Connector shall be as short as possible. The entire length shall be readily accessible for inspection, cleaning, and replacement.

The length of horizontal uninsulated Vent Connector between chimney and a single gas utilization equipment shall not exceed 75% of the the height of the chimney above the connector, or 100% if the Vent Connector is insulated.

The Vent Connector shall be installed so as to avoid turns or other construction features which create excessive resistance to flow of vent gas. It shall be installed without any dips or sags and shall slope upward at least 1/4" per foot.

A manually operated damper shall not be placed in the Vent Connector or chimney of any gas utilization equipment.

The Vent Connector shall be firmly attached to draft hood outlets and flue collars. Joints between sections of connector piping shall be fastened by sheet-metal screws or other approved means. The Vent Connector shall be supported for the design and weight of the material employed to maintain clearance and prevent physical damage and separation of joints.

A draft hood or a barometric draft regulator shall be installed in the same room or enclosure as the equipment ins such a manner as to prevent any difference in the pressure between the hood or regulator and the combustion air supply (see Figures 3 and 4). In no case shall the relief opening of the draft hood or barometric draft regulator be located at a point lower than the top of the highest flue passage in the equipment.

Gas utilization equipment requiring controlled draft may be equipped with a listed double acting barometric draft regulator, If approved by local codes (see Figure 4).

A device which will automatically shut off gas to the burner in the event of sustained backdraft is required. It shall be of the listed manual reset type and installed and adjusted by a qualified service technician in accordance with the manufacturer’s instructions.

Refer to gas utilization equipment manufacturer for recommended vent connection requirements.

FIGURE 1  Dry Base Boiler with Combustion Chamber Liner (Warm Air Furnace Construction is Similar)

FIGURE 2  Wet Base Boiler with Unlined Combustion Chamber

FIGURE 3  Recommended Locations for Draft Hoods
threading burrs or defects. Black pipe and malleable fittings free of cutting and threading defects must not connect to the bottom of a horizontal section. Use new black pipe and malleable fittings close to the gas meter as possible. Do not exceed the 14.0 W.C. maximum, a suitable high pressure regulator must be installed ahead of the Main Pressure Reducing Regulator. If high pressure regulators are used as substitutes, they must be adjustable down to a minimum burner inlet pressure rating (14.0 W.C.)

VI ELECTRICAL

CAUTION: Refer to separate wiring diagram included with each burner. Installation wiring and grounding to the burner must conform to local codes, or, in their absence, to the United States National Electric Code, ANSI/NFPA No. 70 latest edition; in Canada, to Canadian Electrical Code Part 1, CSA Standard C22.1. Use copper wire not less than 14 gauge for line voltage wiring. Hook up to a dedicated line with an on-off disconnect switch and a minimum 10 Amp breaker. The frame of the burner should be well grounded. Normally the piping and/or electric conduit will provide sufficient grounding. However, a ground lug is located in control box for positive grounding where insulated pipe couplings are used or where any doubt exists regarding grounding sufficiency.

Confirm that the polarity is correct—hot wire to strip terminal L1, neutral L2—and that the neutral line is not subject to induced low voltage (check L2 to earth ground) from other equipment, as that can cause the electronic flame safeguard to malfunction.

Each installation must include suitable limit control(s). Existing oil burner combination operating and limit controls are normally NOT SUITABLE for gas burner use.

Connect motors used on forced air furnace fans or boiler pumps to a combination limit control and switch. CAUTION: Label all wires prior to disconnection when servicing controls. Wiring errors can cause improper and dangerous operation. Verify proper operation after servicing.

VI PIPING

CAUTION: The available gas pressure should be within the limits shown in SPECIFICATIONS section. Excessive pressure may damage electric valves, regulators and manual valves. If the supply pressure exceeds the 14.0 W.C. maximum, a suitable high pressure regulator must be installed ahead of the Main Manual Shut-Off Valve shown in Figure 5.

The burner gas supply piping should branch off from the main line as close to the gas meter as possible. Do not connect to the bottom of a horizontal section. Use new black pipe and malleable fittings free of cutting and threading burrs or defects.

Provide a sediment trap, union and 1/8" pressure tap in piping close to burner as shown in Figure 5. Use pipe joint compound approved for use with Liquid Petroleum Gases.

Piping must also comply with your local codes.

To obtain the maximum firing rate of 700 MBH, the NATURAL gas supply piping must be sized to provide a minimum of 5.0 W.C. pressure (11.0 W.C. PROPANE) to the inlet of the main safety valve when the burner and all other gas utilization equipment are on. The pilot regulator can be mounted in any position, the main regulator should be mounted upright and in a horizontal run of pipe.

If the burner piping must be rearranged because of space limitation, be sure to carry out the general arrangement shown in Figure 5.

Run full size pipe or tubing from regulator vent openings to outside of building. Provide no traps in the vent lines and terminate away from all doors and windows; also make provisions for keeping rain and foreign objects from entering the vent piping.

When the burner is installed in the vestibule of jacketed equipment, it is recommended that the Safety Shut-Off Valve(s) be left adjacent to the burner within the vestibule and the Main Manual Shut-Off Valve be installed outside.

When high supply gas pressure is encountered, as in the case in many industrial plants, the gas line size can be reduced to allow for a greater pressure drop; however, the size must be sufficient to deliver burner rating pressure.

CAUTION: High gas pressure supply lines require the proper pressure reducing regulators. Install two separate high pressure regulators of the Tight Shut-Off type upstream of the low pressure regulators. One sized for main gas input, and one suitable for the minimum flow regulating capacity of the pilot.

The high pressure regulators may be substituted for the low pressure regulators. If high pressure regulators are used as substitutes, they must be adjustable down to a minimum of 2.0 W.C. outlet pressure for the pilot and 5.0 W.C. for the main gas. If they are additions they must be adjustable down to the maximum burner inlet pressure rating (14.0 W.C.)

DANGER: Explosion hazard. Do not use oxygen for pressure testing. An explosion could occur during initial start up.

CAUTION: Because it is difficult to accurately control pressure during supply pipe leak testing, it is recommended that all low pressure (14.0 W.C. max.) components, both main and pilot, be disconnected during testing. Exposing low pressure regulators and valves, including manual valves, to pressures over 1/2 PSIG (14.0 W.C.) will cause damage and void all warranties.

When the gas supply line is about to be put into service it must be rested to insure that it is gas tight. Use air or inert gas under pressure and test with soap and water or other liquids to locate leaks.

Before gas is turned into the system, a check must be made to see that there are no open fittings and to make sure the burner main and pilot manual valves are closed.

After checking above, purge the gas line up to the burner inlet. Purging the air from the gas supply line at this step will expedite the first light-off.
TABLE 2: Schedule 40 NPT Pipe-Capacity Chart

VII MAIN GAS SPUD SELECTION

Burners are approved for use with NATURAL or PROPANE gas and should be used only with the gas specified on the rating plate.

□ The gas input should be set at the heating rate determined by the building heat loss and/or heating plant survey, but not exceeding the rated maximum input of the gas utilization equipment or Economite burner.

□ Burners are shipped equipped for NATURAL gas; the model 400 with a 11/32 drill spud installed, and the F400 with the spud removed. Compare the gas input required with the spud capacities shown in the spud table and, if necessary, install the spare spud (see Figure 7).

DATA IS APPROXIMATE AND BASED ON "0" OVERFIRE PRESSURE AT SEA LEVEL

1. Input range of spud. Adjust the main regulator to vary the manifold gas pressure and burner input within the range shown for a specific spud drill size. With PROPANE, do not exceed 11.0"W.C. under any circumstances.

2. Approximate gas pressure at manifold gas pressure tap.

3. Drill out 25/64 spare spud to 7/16.

TABLE 3: Spud Capacity and Preliminary Gas Settings.

FIGURE 5 Piping Connections
VIII INITIAL START UP AND ADJUSTMENT

WARNING: Ignition is automatic. Make spark observations into combustion chamber only with Main and Pilot Manual Shut-Off Valves closed. Confirm that gas utilization equipment does not contain any accumulated gases. Purge as described below.

CAUTION: Cover plates, guards, and enclosures must be maintained in place at all times except during maintenance and service.

1. Check the piping and valves for gas leaks. Apply a weak liquid soap solution to unions and joints with the gas supply on. Leakage will be indicated by the appearance of soap bubbles. Locate and correct all gas leaks before proceeding.

WARNING: DO NOT USE OPEN FLAME

2. Make sure that the burner main and pilot gas lines are completely purged of air. Do not purge into the combustion chamber.

3. Make sure the burner power switch is off, Main and Pilot Manual Shut-Off Valves are closed, and motor is free to rotate. Reset flame safeguard and all limit controls.

CAUTION: Make sure that the capacity range of the installed spud and the combustion air-shutter setting are suitable for the gas utilization equipment. Refer to Section VII and Table 2.

4. Turn on the burner power switch, and allow motor to run through the pre-purge and ignition cycle. Check the blower wheel for proper rotation. After a short run, the flame safeguard will lock out, stopping the motor. Wait one minute, then reset flame safeguard.

5. Turn on pilot manual shut-off valve. With Main Manual Shut-Off Valve still closed, turn on main line switch. Motor will start. When pre-purge period has elapsed, flame safeguard will energize pilot solenoid valve and ignition transformer. Quickly observe pilot flame. When flamerod senses pilot flame, the flame safeguard will energize the main valves. No main flame will occur due to closed Main Manual Shut-Off Valve. Set pilot pressure to the manifold gas pressure required from Table 3 and adjust the main gas pressure regulator accordingly. See Section XI.

6. Test for ignition and stability. Cycle the burner several times with both open and closed air shutter. Ignition and flame safeguard response will be prompt with a good flame. Check flame following the instructions provided by the flame safeguard manufacturer.

WARNING: Repeated unsuccessful attempts to light may result in accumulated gases in gas utilization equipment and chimney. To prevent these gases from reaching an explosive level, periodically purge the gas utilization equipment and chimney as described above.

7. Check operation of the electronic flame detection circuit by turning off the pilot manual valve with pilot burning and Main Manual Shut-Off Valve still closed. The circuit to the main automatic pilot valve should be broken immediately.

8. Turn off line switch to stop the burner. Reset flame safeguard. With On-Off burners, lock air shutter wide open. On modulating burners, remove wires of modulating controller from and "W" terminals on the modulating motor and jumper terminals "R-B" to drive input adjuster to high fire position when energized. On 2-step burners, jumper terminals "3-4" on valve actuator valve will open to high fire position when energized. main flame ignites. Slowly continue opening the Main Manual Shut-Off Valve to the wide open position when energized.

9. To make a preliminary setting of the burner input, determine the manifold gas pressure required from Table 3 and adjust the main gas pressure regulator accordingly. See Section XI.

10. To determine the firing rate for NATURAL gas, accurately time test dial for the number of seconds for one revolution and use the following formula. All other gas utilization equipment must be off.

\[
\text{3600 x test dial size x BTU value} \div \text{no. of seconds for one rev. test dial} = \text{BTU/Hr.}
\]

Then divide by 1,000 for MBH value.

Example: \[
\frac{3600 \times 1 \times 1000}{10} = 360,000 \text{ BTU/Hr.} = 360 \text{ MBH}
\]

11. Adjust combustion air shutter to provide a quiet, soft blue flame with well defined orange and yellow tips for NATURAL gas or with well defined yellow tips for PROPANE gas.

12. The primary air adjustment which affects the flame length has been set wide open for average conditions. Decrease the primary air if a longer, softer flame is desired.

13. Check the operation of the burner; start and stop it several times with the thermostat or operating control.

14. With the burner running, check the operation of all limit and associated controls.

15. PERFORM THE FOLLOWING FINAL ADJUSTMENTS for combustion and flue gas temperatures. Take the flue gas samples and temperature immediately ahead of the draft control.

A. The flue gas temperature should be above 325°F but not exceeding 550°F. Excessive flue gas temperatures will result in low efficiencies. Low flue gas temperature may cause excessive condensation. Reset gas input if necessary to adjust stack temperature.

B. Make the final setting of the combustion air shutter by checking the flue gases with an ORSAT or similar combustion testing instrument. The carbon monoxide content should conform to local codes, or, in their absence to the level specified in the United States or Canadian Standard referenced on the front cover of this manual. The carbon dioxide content should be approximately 9.5% for NATURAL and 12.1% for PROPANE, or within the limits prescribed by local codes.

16. Check the draft control to make sure there is no spillage of flue products into the room.
After the initial start-up procedure, the following steps can be followed for routine start-up and shut-down on a seasonal or extended basis.

**BURNER START UP**
1. Make sure burner power switch is off.
2. Set controller to call for heat.
3. Open firing door.
5. Reset flame safeguard.
6. Turn on burner power switch.
7. Close firing door after main flame ignites.
8. Reset controller to desired setting.

**BURNER SHUT DOWN**
1. Turn off burner power switch.
4. Disconnect motor wires, and completely remove the side plate, motor and blower wheel assembly.
5. Motor cooling air vents if present should also be cleaned at this time.
6. Both the spark and flame rods are currently carrying conductors and, along with their connecting wires, must be kept free of contact with conductive metal parts of the burner. Rod insulators and wire insulator should be clean, dry and free of cracks.
7. CAUTION: The pilot gas orifice is the same size for both natural and propane gas, consequently the gas pressure required for propane is lower than that required for natural gas. Under normal conditions, with a slight negative pressure in the combustion chamber, pilot operating pressures are 3.5”W.C. NATURAL gas and 2.25”W.C. PROPANE.
8. Some conditions which may require a change from the normal setting include: extremely long tubing connections between the regulator and pilot solenoid, high negative or positive combustion chamber pressure, actual air shutter setting and altitude extremes.
9. Do not subject the pilot to an inlet pressure over 14.0”W.C. See section VI PIPING for high pressure gas. Note that the standard pilot pressure regulator is not a tight shut-off and, during standby, the outlet pressure will build up to the full inlet pressure.
10. The spark rod is located on the center line of the pilot and is positioned so the high tension voltage will arc to the inside of the center port of the retention plate (see Figure 7).
11. The flame rod must be positioned as shown in Figure 7 so that the flame safeguard will detect a proper flame. Note that it is slightly above the centerline of the pilot.
12. Both the spark and flame rods are currently carrying conductors and, along with their connecting wires, must be kept free of contact with conductive metal parts of the burner. Rod insulators and wire insulator should be clean, dry and free of cracks.
13. rods are made from heat resistant alloys and can be expected to have a long service life. They should be routinely inspected, however, for corrosion or loss of metal. 
14. The pilot air tube must be kept free of kinks or inside obstructions and its inlet end must be positioned per Figure 7, otherwise air flow could be reduced and adversely affect the pilot flame.

**PART 2 SERVICE**

**DANGER:** Do not tamper with the unit or controls. If trouble occurs contact the installing contractor, service agency, or fuel supplier. See front cover.

**WARNING:** Be sure that the main and pilot manual Shut-Off Valves are closed and the burner power supply is turned off before removing any parts for service.

**CAUTION:** Cover plates, guards, and enclosures must be maintained in place at all times except during maintenance and service.

**IX PILOT**
The pilot is of the premix, blast type. The full force of blower air is brought into the mixing tube where the proper amount of gas is added through the pilot orifice. This mixture is discharged through the pilot which contains a perforated flame retention plate. The outer holes diverge to spray the mixture against the side wall of the pilot tip to provide flame retention. The mixture through the center port provides the flame that contacts the lot tip to provide flame retention. The mixture through the orifice size. Pilot troubles are rarely cured in this manner and new troubles may be created.

The pilot gas orifice is the same size for both natural and propane gas, consequently the gas pressure required for propane is lower than that required for natural gas. Under normal conditions, with a slight negative pressure in the combustion chamber, pilot operating pressures are 3.5”W.C. NATURAL gas and 2.25”W.C. PROPANE.

Some conditions which may require a change from the normal setting include: extremely long tubing connections between the regulator and pilot solenoid, high negative or positive combustion chamber pressure, actual air shutter setting and altitude extremes.

Do not subject the pilot to an inlet pressure over 14.0”W.C. See section VI PIPING for high pressure gas. Note that the standard pilot pressure regulator is not a tight shut-off and, during standby, the outlet pressure will build up to the full inlet pressure.

The spark rod is located on the center line of the pilot and is positioned so the high tension voltage will arc to the inside of the center port of the retention plate (see Figure 7).

The flame rod must be positioned as shown in Figure 7 so that the flame safeguard will detect a proper flame. Note that it is slightly above the centerline of the pilot.

Both the spark and flame rods are currently carrying conductors and, along with their connecting wires, must be kept free of contact with conductive metal parts of the burner. Rod insulators and wire insulator should be clean, dry and free of cracks.

Rods are made from heat resistant alloys and can be expected to have a long service life. They should be routinely inspected, however, for corrosion or loss of metal.

The pilot air tube must be kept free of kinks or inside obstructions and its inlet end must be positioned per Figure 7, otherwise air flow could be reduced and adversely affect the pilot flame.

**X MOTOR, BLOWER INTERLOCK & CENTRIFUGAL ACTUATOR**

**CAUTION:** BEFORE SERVICING, mark with a scribe line or measure position of combustion air controlling shutter, so that it can be reset to its original position following servicing.

The blower, which is driven by the motor, functions to supply a constant and dependable source of combustion air. A centrifugal actuator is mounted on the blower wheel and, through the interlock switch, proves blower operation on every run.

Cleaning of the blower wheel is usually the only service required. Need for cleaning is indicated if the air cage assembly shows an accumulation of dust and lint, or if the character of the flame indicates a deficiency of air. Motor cooling air vents if present should also be cleaned at this time.

The blower side plate, motor and wheel are removed as an assembly. Disconnect the motor wires, and conduit then remove the side plate screws.

Unless the blower wheel location has been disturbed, a replacement switch and bracket assembly will assume the correct position when mounted. Confirmation of the correct assembly can be made by measurement and test.

A) With the switch assembly unmounted, insert a probe through the blower opening and push actuator disk inward as far as it will go. Mark the depth of insertion on the probe and measure. Measure the portion of the switch plunger (unrestrained) protruding past the bracket arms. The probe insertion measurement should exceed the switch stem protrusion by at least 1/16".

  - **BURNER SHUT DOWN**
  - **PART 2 SERVICE**
  - **IX PILOT**
  - **X MOTOR, BLOWER INTERLOCK & CENTRIFUGAL ACTUATOR**
  - **TABLE 4:** Pilot Specifications
The vent must be connected and disconnected.

checked by comparing main flame start-up time with the sluggish opening of the regulator. The effect can be diameter, otherwise the restriction of air flow may cause ruptured diaphragm. The vent line must be of sufficient air to prevent escape of gas into the building in case of a breathes only air, but must be connected to the outside special regulators are required. See Section VI.

To adjust the outlet pressure, remove the seal cap for access to the adjusting screw. Turning the screw clockwise will increase outlet pressure, counter-clockwise will decrease outlet pressure.

When the gas supply pressure is over 14.0"W.C., special regulators are required. See Section VI.

The vent in the upper diaphragm case normally breathes only air, but must be connected to the outside air to prevent escape of gas into the building in case of a ruptured diaphragm. The vent line must be of sufficient diameter, otherwise the restriction of air flow may cause sluggish opening of the regulator. The effect can be checked by comparing main flame start-up time with the vent line connected and disconnected. The vent must never be connected to the burner combustion chamber.

When the regulator is to be installed, or replaced take care not to crush the body casting. Apply wrench only to the heavy body section adjacent to the pipe thread.

When shaft location of blower wheel is disturbed, reassemble with a 1/16" clearance as shown in Figure 6.

XI GAS PRESSURE REGULATOR
The main gas pressure regulator is used to automatically reduce and maintain constant gas pressure at the burner. The regulator furnished as standard is suitable for a maximum inlet pressure of 14.0"W.C. The springs installed provides for an adjustable outlet pressure range of 2.0" to 5.0"W.C. and are factory set for 3.0"W.C. This regulator is not of the "tight shut-off" type and, consequently, when the burner is on standby, the outlet pressure will build up to equal the full inlet line pressure. Outlet pressure settings must be checked while the main gas is flowing.

To adjust the outlet pressure, remove the seal cap for access to the adjusting screw. Turning the screw clockwise will increase outlet pressure, counter-clockwise will decrease outlet pressure.

When the gas supply pressure is over 14.0"W.C., special regulators are required. See Section VI.

The vent in the upper diaphragm case normally breathes only air, but must be connected to the outside air to prevent escape of gas into the building in case of a ruptured diaphragm. The vent line must be of sufficient diameter, otherwise the restriction of air flow may cause sluggish opening of the regulator. The effect can be checked by comparing main flame start-up time with the vent line connected and disconnected. The vent must never be connected to the burner combustion chamber.

When the regulator is to be installed, or replaced take care not to crush the body casting. Apply wrench only to the heavy body section adjacent to the pipe thread.

XII SOLENOID GAS SAFETY VALVES
(Main and Redundant Main; Standard Construction.) When the valve operators are electrically energized the plungers lift the valve disk off the valve seats, allowing gas to flow. When the current is broken the valves close. They will normally require no service. However, dirt or foreign matter on the valve seats could cause leakage. If leakage is detected or if the operator malfunctions re-place the entire valve. After replacement check for leakage. If the valve is removed from the piping do not use the operator assembly as a lever to turn valve. Apply wrench on the valve body flat adjacent to pipe being removed.

XIII OPTIONAL MOTORIZED MAIN
AUTOMATIC VALVE
(Employed with Redundant Solenoid Valve.)

When the actuator is energized, hydraulic fluid is pumped from a reservoir to a metal bellows. The bellows transfers the resulting pressure through the drive stem to open the valve. A separate spring return drive arm operates the blower shutter.

For general service, the valve should be checked for operation. The valve actuator may be removed from the valve body, however, do not disassemble actuator; if malfunction occurs, replace entire actuator assembly. The valve body is also not field reparable. If leakage is detected the entire valve body must be replaced.

XIV FLAME SAFEGUARD

WARNING: Explosion hazard. Do not use any electronic device if it gets wet. It can malfunction and cause serious injury or death. Replace any device that has been wet.

Standard F400-33 and 400-33 burners are equipped with a Honeywell RM7895 microprocessor based burner control, employing a flame rectification system of flame detection. Burner construction for special codes and/or insurance requirements such as Factory Mutual or Industrial Risk Insurers (IRI) may require alternate controls. (Refer to Section XV Special Equipment). A safe start and run control sequence is provided with instantaneous response to presence or loss of flame signal. Flame failure response time is 3-seconds.; Pilot Flame Establishing Period (PFEP) is field selectable from 4 or 10-seconds. The RM7895 features a pre-purge time (30-seconds for ON-OFF, 90-seconds for 2-Step or Modulating burners), and a plug-in amplifier. An airflow circuit is also field selectable to allow either lockout or recycle upon loss of airflow. Five LED’s (light emitting diodes) are provided to display sequence information. Refer to the Honeywell RM7895 literature for detailed operating information, configuration requirements, testing, and service.
After the ignition trials, and with the presence of flame, the main valve is energized. ("MAIN" LED will be lit.) If a flame-out occurs, the RM7895 will lockout or recycle within 3-seconds, depending on "jumper" configuration. Refer to Honeywell literature for proper configuration.

**STANDBY ("POWER" LED is lit).**
- The RM7895 is idle in this state of sequencing. When the burner switch, limits, operating limit controls, and all microprocessor monitored circuits are in the correct state for the RM7895 to continue, sequencing will advance to PREPURGE.

**PREPURGE ("POWER" LED is lit).**
- The RM7895 in this application features a prepurge time of 30-seconds for ON-OFF, 90-seconds for 2-Step or Modulating burners.
- Once the STANDBY sequence has a "CALL FOR HEAT" input, normal start-up prepurge will be initiated.
  - The airflow interlock switch must close in ten seconds of prepurge or within the specified purge card timing. Otherwise a recycle to the beginning of prepurge or lockout will occur, depending on how the airflow switch selectable jumper is configured. Refer to Honeywell RM7895 literature for configuration requirements.

**IGNITION TRIAL**
1. PILOT FLAME ESTABLISHING PERIOD (PFEP)
   - The pilot valve and spark generator are energized.
   - Flame must be proven by the end of the 4 or 10-second PFEP to allow the sequence to continue. If flame is not proven by the end of PFEP, a safety shutdown occurs.
2. MAIN FLAME ESTABLISHING PERIOD (MFEP)
- After the ignition trials, and with the presence of flame, the main valve is energized. ("MAIN" LED will be lit.) If a flame-out occurs, the RM7895 will lockout or recycle within 3-seconds, depending on "jumper" configuration. Refer to Honeywell literature for proper configuration.

**RUN**
- The RM7895 is now in RUN mode and will remain in run mode until the controller input opens, indicating that the call for heat has been satisfied or a limit has opened. Once this occurs the RM7895 will sequence back to the STANDBY mode.

**Notes:**
1. During STANDBY and during RM7895 sequencing the "POWER" LED will blink every four seconds. This is normal.
2. The "ALARM" LED will be lit in the event of any flame failure.
3. To maintain proper operation of this device in MUST be electrically grounded. Refer to Honeywell RM7895 literature for criteria.

**XV SPECIAL EQUIPMENT (OEM VERSIONS)**
Special equipment, either factory or field installed, can cause variations in the procedures and descriptions given in this manual. Generally, any burner ordered with special factory installed equipment will be supplied with the appropriate wiring diagram and related instruction manuals from the special equipment manufacturer. Consult these manuals to identify any differences in construction, operation, and testing. Field installed special equipment is the responsibility of the installing contractor.
TROUBLE CHART

MAKE SURE THE THERMOSTAT AND OPERATING CONTROLS ARE CALLING FOR HEAT.

⚠️ CAUTION: If a test indicates an electrical component may be defective, before replacing it, make sure that its associated wiring is not at fault.

1. MOTOR WILL NOT RUN.
   A. No current.
   B. Defective or misadjusted limit or thermostat.
   C. Flame safeguard control on lockout.
   D. Defective flame safeguard control.
   E. Motor overload out.
   F. Defective motor.
   G. Defective flame rod or wire.
   H. Flame rod mislocated.
   I. Spark interference.
   J. Pilot regulator vent clogged.
   K. Defective plug-in amplifier.
   L. Defective flame safeguard.

2. MOTOR RUNS, PILOT WILL NOT LIGHT, FLAME SAFEGUARD LOCKS OUT.
   A. Air in pilot gas line.
   B. Low gas pressure.
   C. Clogged pilot orifice.
   D. Pilot regulator misadjusted or defective.
   E. Defective spark electrode or spark generator.
   F. Defective high tension wire.
   G. Wrong pilot orifice.
   H. Defective pilot valve.
   I. Pilot air tube clogged.
   J. Incorrect spark gap.
   K. Pilot regulator vent clogged.
   L. Defective main gas valve.
   M. Closed leak test cock.
   N. Low gas pressure.
   O. Grossly misadjusted main gas and air.
   P. Defective flame safeguard.

3. MOTOR RUNS, PILOT WILL NOT LIGHT, FLAME SAFEGUARD REMAINS "SET."
   A. Defective centrifugal actuator.
   B. Defective blower interlock switch.
   C. Slow motor.
   D. Defective purge timer.
   E. False flame signal; flame safeguard control.
   F. Defective flame safeguard.

4. PILOT LIGHTS, NO MAIN FLAME, RELAY LOCKS OUT.
   A. Poor pilot flame adjustment.
   B. Clogged pilot air tube.
   C. Defective main gas valve.
   D. Closed leak test cock.
   E. Low gas pressure.
   F. Grossly misadjusted main gas and air.
   G. Defective flame safeguard.

5. PILOT LIGHTS, NO MAIN FLAME, RELAY REMAINS "SET."
   A. Defective main gas valve.
   B. Closed leak test cock.
   C. Low gas pressure.
   D. Grossly misadjusted main gas and air.
   E. Defective flame safeguard.

6. SPASMODIC START.
   A. Loose wiring.
   B. Low gas pressure.
   C. Poor pilot flame adjustment.

7. SHORT FLAME.
   A. Wrong main orifice.
   B. Low gas pressure.
   C. Air shutter misadjusted.
   D. Main regulator misadjusted.
   E. Test cock partially closed.
   F. Main regulator vent clogged.

8. LONG HAZY FLAME.
   A. Wrong main orifice.
   B. High gas pressure.
   C. Dirty blower wheel.
   D. Air shutter misadjusted.
   E. Main regulator misadjusted.

9. GAS FAILS TO SHUT OFF.
   A. Dirt on valve seat(s).
   B. Defective main valve(s).
